L^AT_EX: A Universal Syntax for Math Equations

Display math equations in browsers:

WYSIWYG editors like MS Word supports (partial) L^AT_EX syntax¹:

¹This gif is made using the animate package, to view it correctly, open in Acrobat Reader/KDE Okular/PDF-XChange/Foxit Reader.

L^AT_EX syntax is Cryptic and Mysterious

A novice user expects $y^{123} + x$

types “\$y^123+x\$”

but got **unexpected** $y^123 + x$ (superscript is wrong!)

How to Fix Errors?

Possible methods:

- ① Resort to search engine/online help forum
 - ▶ Properly describe the issue
 - ▶ **Adapt** the solution (if found)
- ② QuickFix: a **fixed** set of **human-specified** rules
- ③ Our approach (**EqFix**): rule-based, but **automatically** learned from a **small** set of examples

Programming by Examples (PBE)

Input Output

x_1 y_1

x_2 y_2

\vdots

\vdots

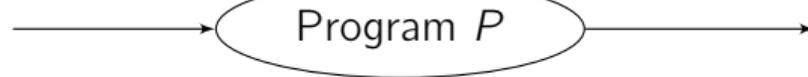

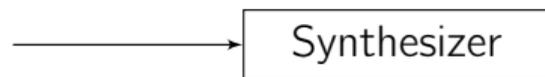

Input Output

t_1 ?

t_2 ?

\vdots

\vdots

Input Output

t_1 $P(t_1)$

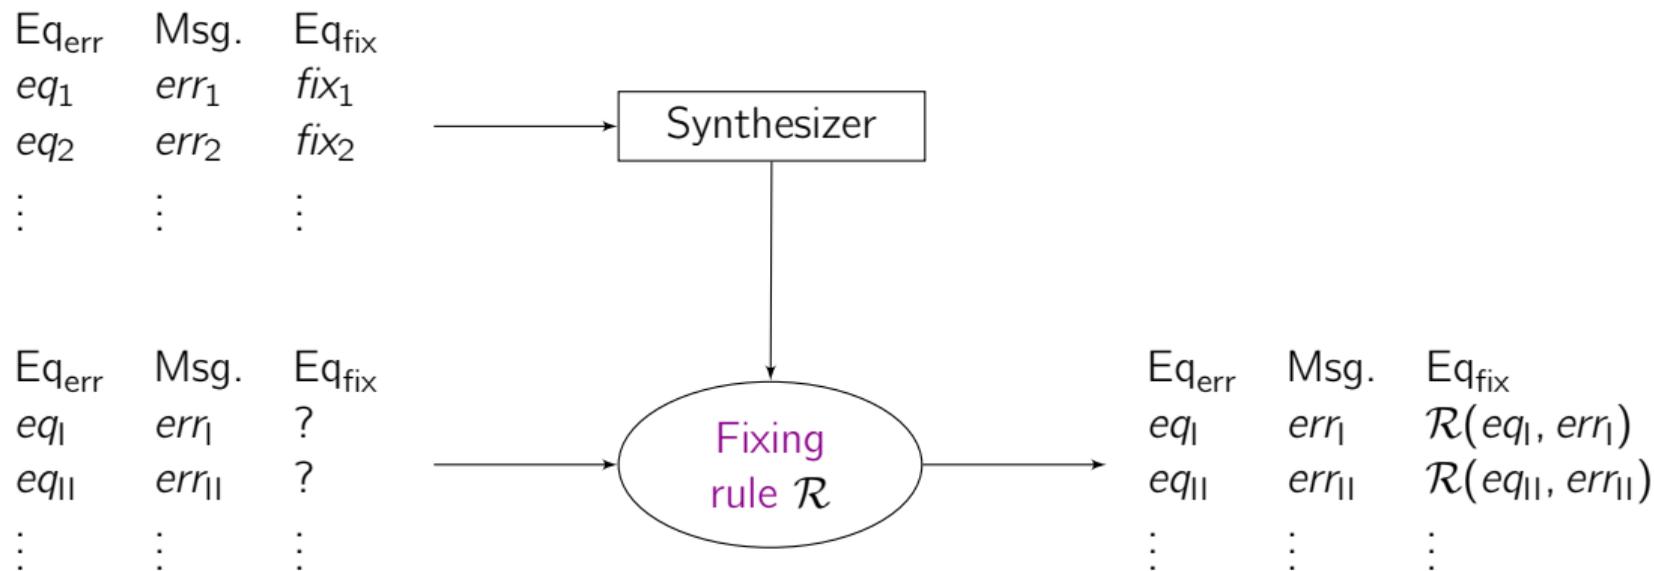

t_2 $P(t_2)$

\vdots

\vdots

Soundness: P is **consistent** with the input-output examples, i.e., $\forall i, P(x_i) = y_i$

PBE for Fixing \LaTeX Equations

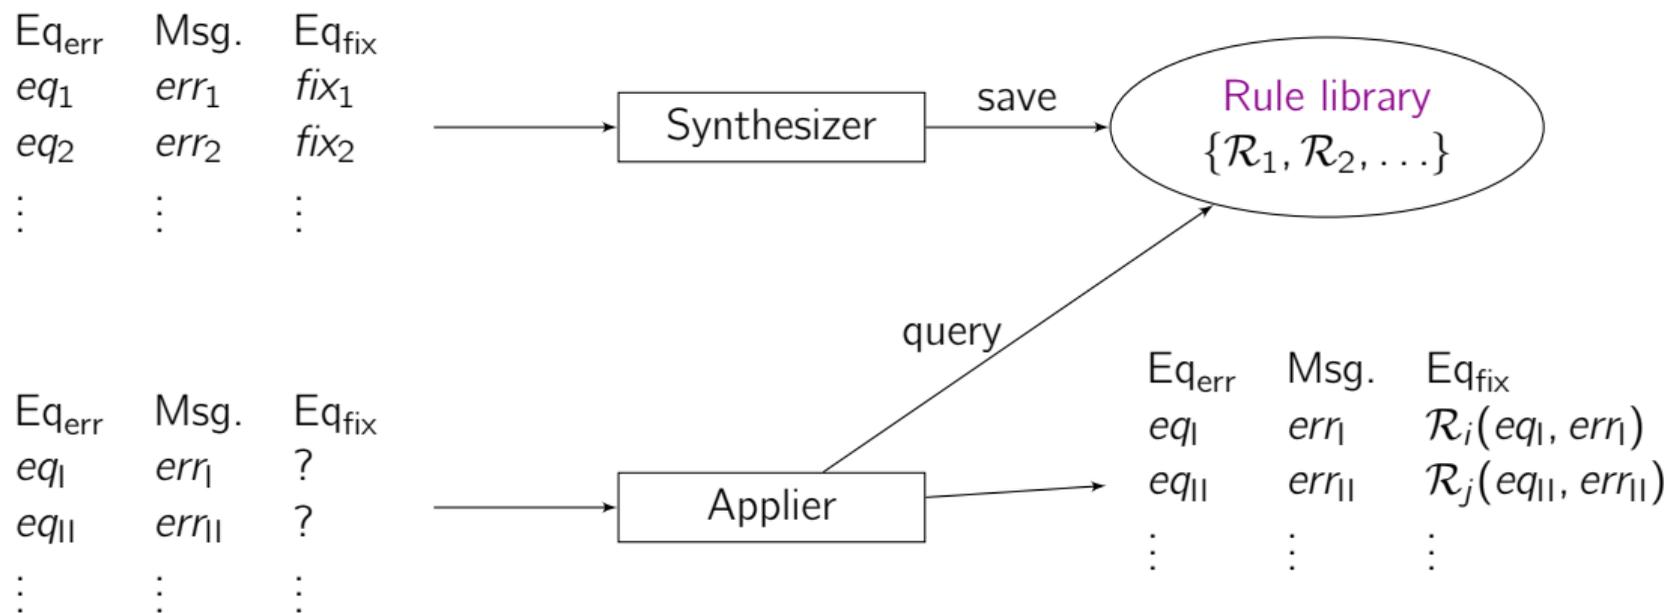

Program: Fixing rule

Input: Erroneous equation (Eq_{err}) + Error message (Msg.)

Output: Fixed equation (Eq_{fix})

Fixing Rules Maintained in Library

Fixing Rule

A (fixing) rule \mathcal{R} consists of two components:

- An **error pattern** is a template of the error message
- A **transformer** specifies the required string transformation on the erroneous parts

Rules are learned from examples!

Input-Output Examples for EqFix

An **input-output example** consists of an erroneous equation, an error message, and a fixed equation.

Example

#1

eq_1 : x^{10} x^{10}

err_1 : superscript 10

fix_1 : $x^{\{10\}}$ x^{10}

#2

eq_2 : $y^{123}+x$ $y^{123} + x$

err_2 : superscript 123

fix_2 : $y^{\{123\}}+x$ $y^{123} + x$

Fixing Rule (Example)

#1	#2
$eq_1 : \$x^{10}\$$	$eq_2 : \$y^{123}+x\$$
$err_1 : \text{superscript } 10$	$err_2 : \text{superscript } 123$
$fix_1 : \$x^{\{10\}}\$$	$fix_2 : \$y^{\{123\}}+x\$$

Example

A fixing rule consistent with #1 (and also #2): $\mathcal{R}_1 = \langle EP_1, \mathcal{T}_1 \rangle$ where

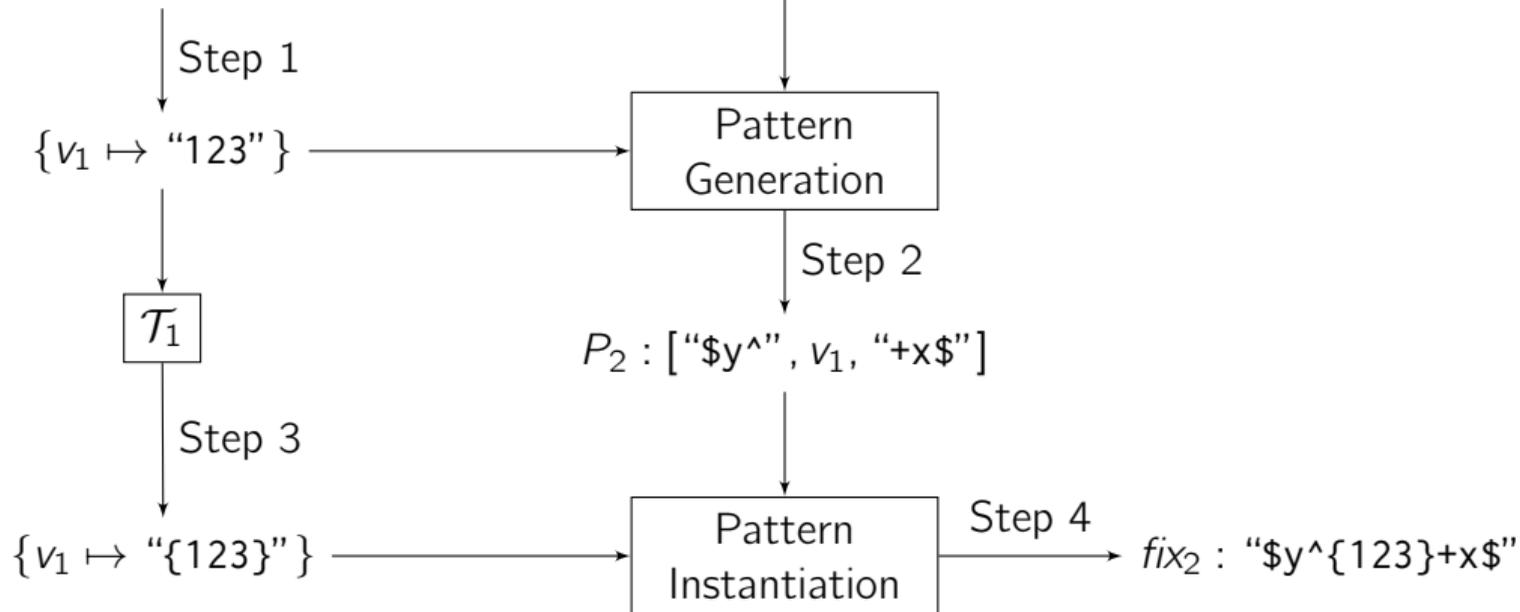

- the error pattern $EP_1 = [\text{"superscript"}, v_1]$ has one **variable** v_1
- the transformer $\mathcal{T}_1 = \{v_1 \mapsto f_1\}$ has one underlying **string transformer** (a function of type $\text{string} \rightarrow \text{string}$) $f_1(x) = \text{"{"} + x + \text{"}"}$

Rule Application

$$\mathcal{R}_1(eq_2, err_2) = fix_2$$

$err_2 : ["superscript", "123"]$

$EP_1 : ["superscript", v_1]$

Step 1: Extract Problem-Specific Information

$err_2 : ["superscript", "123"]$

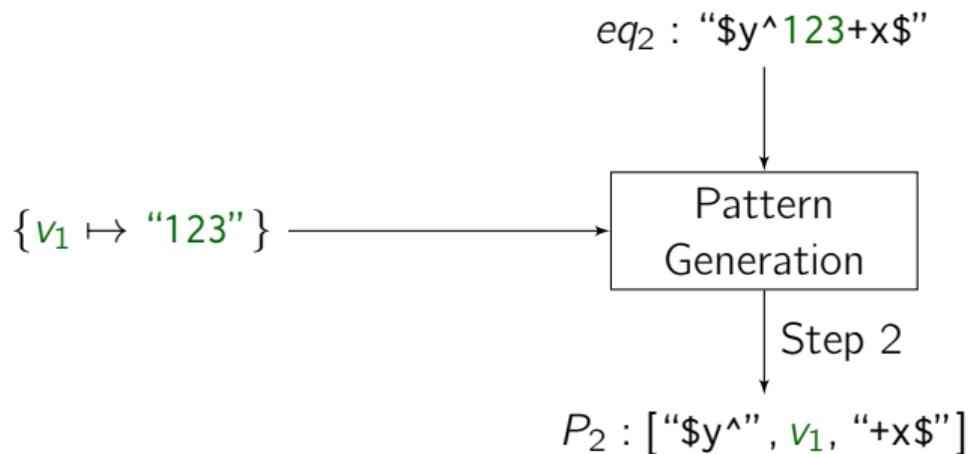

$EP_1 : ["superscript", v_1]$

↓ Step 1

$\{v_1 \mapsto "123"\}$

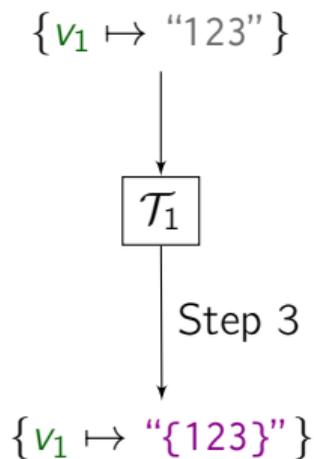

Match the error pattern against the concrete (tokenized) error message: obtain a **mapping** from variables to values.

Step 2: Equation Pattern Generation

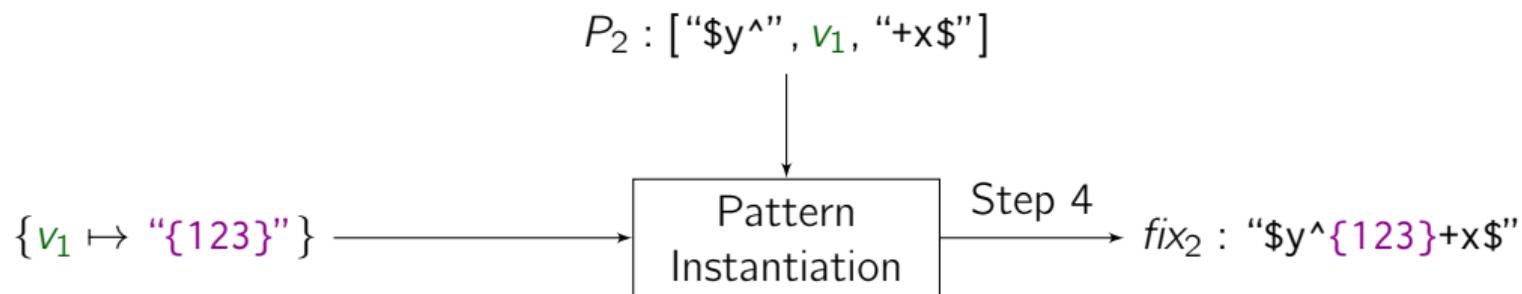

Abstract over the erroneous equation into an **equation pattern**—this pattern matches both the erroneous and the fixed equation.

Step 3: Transformation on Extracted Values

Apply the underlying string transformer for each variable: obtain a **new mapping** with transformed values.

Step 4: Equation Pattern Instantiation

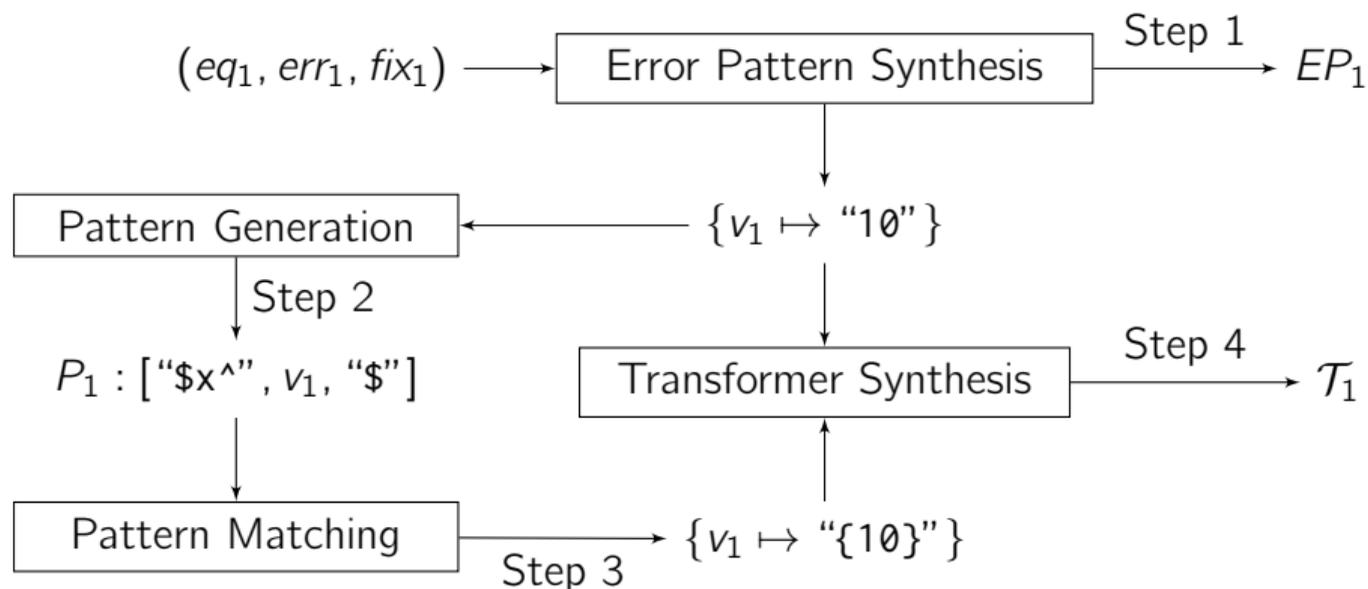

Instantiate the equation pattern with the new mapping: produce the fix.

Rule Synthesis

Learn \mathcal{R}_1 by example (eq_1, err_1, fix_1)

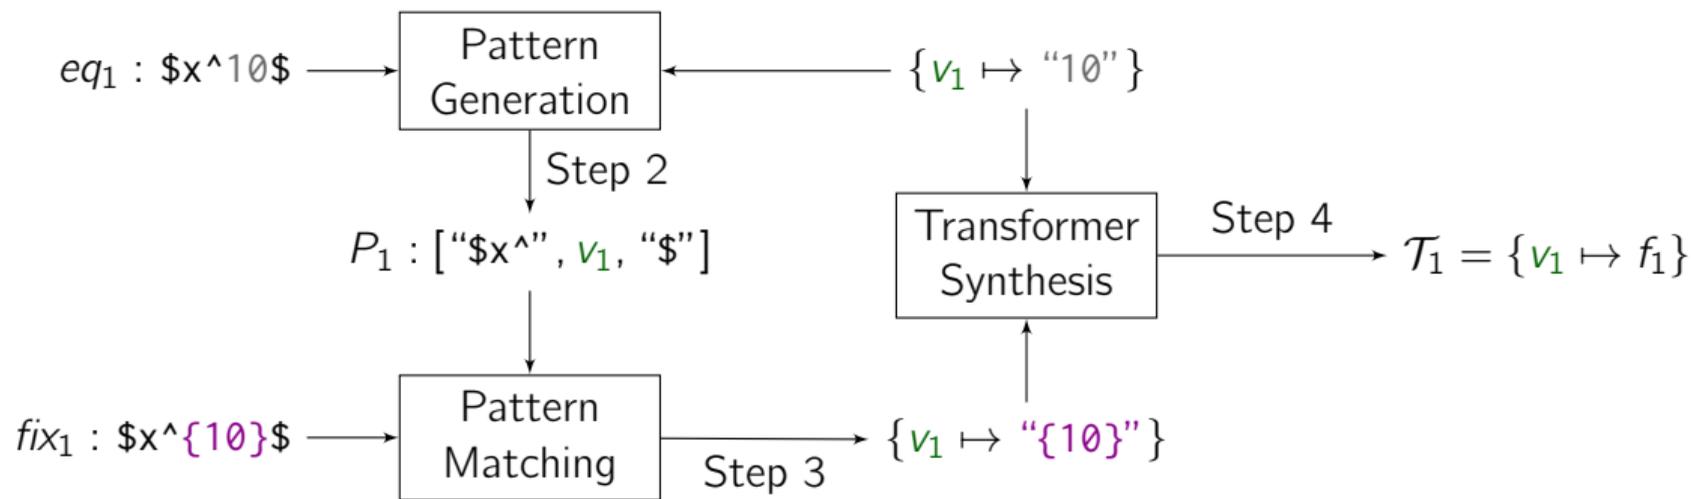

Error Pattern Synthesis

Replace tokens of the error message that occur in the input/output equation as variables in the error pattern.

Transformer Synthesis

The specification for synthesizing f_1 is a set of string input-output examples $\{"10" \mapsto "\{10\}"\}$. We adopt FlashFill's [Gul11] approach for the synthesis.

More on our paper and extended version [ZH22]:

- Formal definition of fixing rules
- Synthesis procedures

Evaluation Setup

Baseline: FlashFill (Implementation in PROSE²)

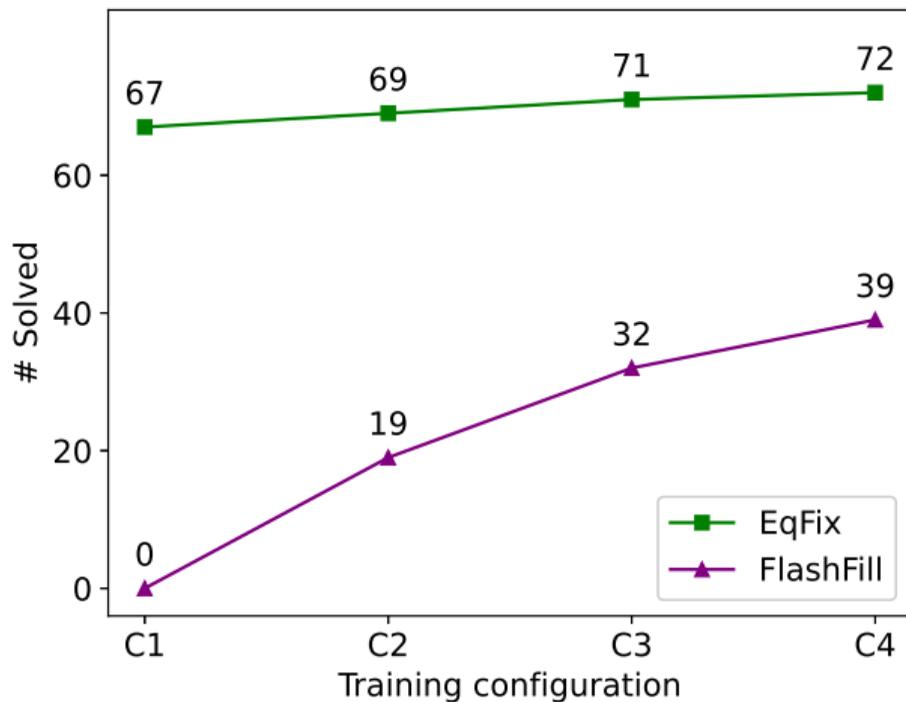

Dataset: 89 examples groups; for each example group:

- take the shortest 1-4 (C1-C4) examples for learning/training
- take the longest for testing

#	Training				Testing
1	Example 1-1	Example 1-2	Example 1-3	Example 1-4	Example 1-5
2	Example 2-1	Example 2-2	Example 2-3	Example 2-4	Example 2-5

Solved Testcases

Configuration C_i : learning from the first i examples (for each group).

EqFix Simplifies String Transformer Synthesis

To learn a rule from:

eq_1 : x^{10}

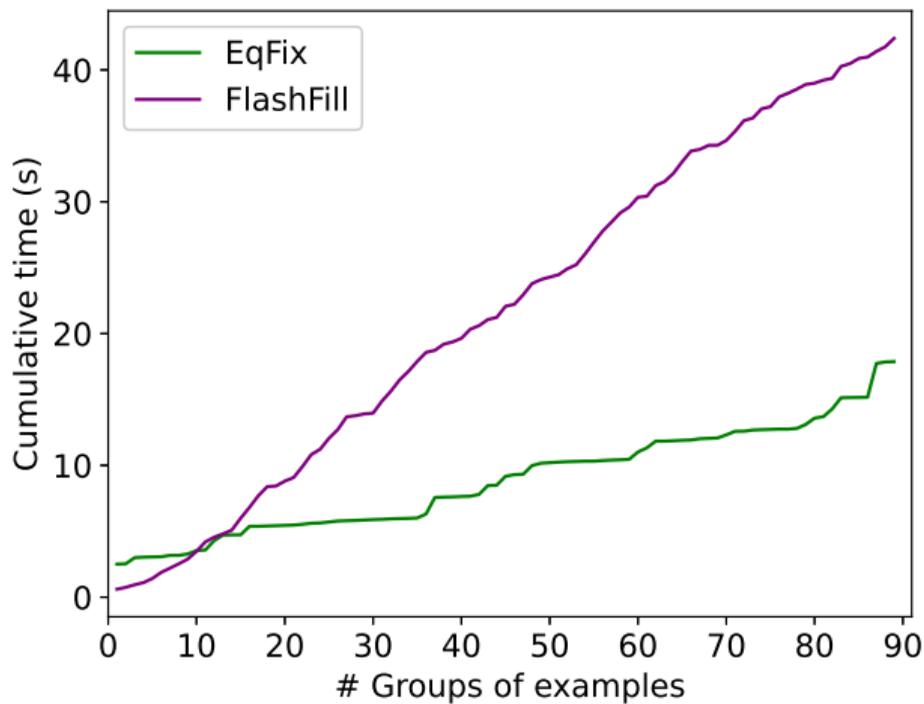

err_1 : superscript 10

fix_1 : $x^{\{10\}}$

- FlashFill needs to learn a string transformer for $(“x^{10}”, err_1) \mapsto “x^{\{10\}}”$
- EqFix needs to learn a string transformer for $“10” \mapsto “\{10\}”$

Cummulative Synthesis Time

Under configuration C4

Enabling Rule Library

Train and save rules to an XML file:

Load rules from that XML file and test:

The screenshot shows the GitHub repository page for 'EqFix'. At the top, it says 'README.md'. The main heading is 'EqFix'. Below the heading, there is a green badge that says 'CI passing'. The description reads: 'Repairing LaTeX equations by examples.' The next section is 'System Requirements', which states: 'Install .NET SDK (<https://www.microsoft.com/net/download>) for your platform. You must have .NET Core 2.x installed to correctly run PROSE's DSL compiler.' A note follows: 'Note: you may build this project using a higher version .NET SDK (such as 6.x, the latest); but 2.x must be one of your installed version. Type `dotnet --list-sdks` to check if 2.0.x/2.1.x/2.2.x is on the list.' The final section shown is 'Build'.
